Daniela Jiménez Téllez - A01654798

Using Pre-trained Word Embeddings

In this notebook we will show some operations on pre-trained word embeddings to gain an intuition about them.

We will be using the pre-trained GloVe embeddings that can be found in the official website. In particular, we will use the file glove.6B.300d.txt contained in this zip file.

We will first load the GloVe embeddings using Gensim. Specifically, we will use KeyedVectors 's load_word2vec_format() classmethod, which supports the original word2vec file format. However, there is a difference in the file formats used by GloVe and word2vec, which is a header used by word2vec to indicate the number of embeddings and dimensions stored in the file. The file that stores the GloVe embeddings doesn't have this header, so we will have to address that when loading the embeddings.

Loading the embeddings may take a little bit, so hang in there!

Word similarity

One attribute of word embeddings that makes them useful is the ability to compare them using cosine similarity to find how similar they are. KeyedVectors objects provide a method called most_similar() that we can use to find the closest words to a particular word of interest. By default, most_similar() returns the 10 most similar words, but this can be changed using the topn parameter.

Below we test this function using a few different words.

```
In [2]: # common noun
glove.most_similar("cactus")
```

```
[('cacti', 0.6634564399719238),
Out[2]:
          ('saguaro', 0.6195855140686035),

```

Word analogies

Another characteristic of word embeddings is their ability to solve analogy problems. The same $most_similar()$ method can be used for this task, by passing two lists of words: a positive list with the words that should be added and a negative list with the words that should be subtracted. Using these arguments, the famous example $k\vec{ing} - m\vec{a}n + wo\vec{m}an \approx qu\vec{e}en$ can be executed as follows:

```
In [9]: # car - drive + fly
glove.most_similar(positive=["car", "fly"], negative=["drive"])
```

```
[('airplane', 0.5897148251533508),
Out[9]:
          ('flying', 0.5675230622291565),
          ('plane', 0.5317023396492004),
          ('flies', 0.5172374248504639),
          ('flown', 0.5147904753684998),
          ('airplanes', 0.5091356635093689),
          ('flew', 0.5011662244796753),
          ('planes', 0.4970923066139221),
          ('aircraft', 0.4957723915576935),
          ('helicopter', 0.45859551429748535)]
In [10]: # berlin - germany + australia
          glove.most_similar(positive=["berlin", "australia"], negative=["germany"])
         [('sydney', 0.6780861616134644),
Out[10]:
          ('melbourne', 0.6499180793762207),
          ('australian', 0.5948832035064697),
          ('perth', 0.5828552842140198),
          ('canberra', 0.5610731840133667),

In [13]: # best - good + tall
          glove.most_similar(positive=["best", "tall"], negative=["good"])
```

Looking under the hood

Now that we are more familiar with the <code>most_similar()</code> method, it is time to implement its functionality ourselves. But first, we need to take a look at the different parts of the <code>KeyedVectors</code> object that we will need. Obviously, we will need the vectors themselves. They are stored in the <code>vectors</code> attribute.

```
In [14]: glove.vectors.shape
Out[14]: (400000, 300)
```

As we can see above, vectors is a 2-dimensional matrix with 400,000 rows and 300 columns. Each row corresponds to a 300-dimensional word embedding. These embeddings are not normalized, but normalized embeddings can be obtained using the get_normed_vectors() method.

```
In [15]: normed_vectors = glove.get_normed_vectors()
    normed_vectors.shape

Out[15]: (400000, 300)
```

Now we need to map the words in the vocabulary to rows in the vectors matrix, and vice versa. The KeyedVectors object has the attributes index_to_key and key_to_index which are a list of words and a dictionary of words to indices, respectively.

```
In [16]: glove.index_to_key
```

```

Word similarity from scratch

Now we have everything we need to implement a <code>most_similar_words()</code> function that takes a word, the vector matrix, the <code>index_to_key</code> list, and the <code>key_to_index</code> dictionary. This function will return the 10 most similar words to the provided word, along with their similarity scores.

```
import numpy as np

def most_similar_words(word, vectors, index_to_key, key_to_index, topn=10):
    # retrieve word_id corresponding to given word
    word_id = key_to_index.get(word)

# retrieve embedding for given word
```

```
word embedding = vectors[word id]
# calculate similarities to all words in our vocabulary
similarities = np.dot(vectors, word_embedding)
# get word_ids in ascending order with respect to similarity score
word_ids = np.argsort(similarities)
# reverse word ids to have most similar words at the top
word_ids = word_ids[::-1]
# get boolean array with element corresponding to word id set to false
mask = np.ones(len(word_ids), dtype=bool)
mask[word_id] = False
# obtain new array of indices that doesn't contain word_id
word_ids = word_ids[mask]
# get topn word ids
top_ids = word_ids[:topn]
# retrieve topn words with their corresponding similarity score
top_words = [(index_to_key[idx], similarities[idx]) for idx in top_ids]
# return results
return top_words
```

Now let's try the same example that we used above: the most similar words to "cactus".

```
In [23]: vectors = glove.get_normed_vectors()
    index_to_key = glove.index_to_key
    key_to_index = glove.key_to_index
    most_similar_words("cactus", vectors, index_to_key, key_to_index)

Out[23]:

[('cactus', 1.0000002),
    ('cacti', 0.66345644),
    ('saguaro', 0.6195855),
    ('pear', 0.5233487),
    ('cactuses', 0.5178282),
    ('prickly', 0.51563185),
    ('mesquite', 0.4844855),
    ('opuntia', 0.45400846),
    ('shrubs', 0.4536207),
    ('peyote', 0.4534496)]
```

Analogies from scratch

The <code>most_similar_words()</code> function behaves as expected. Now let's implement a function to perform the analogy task. We will give it the very creative name <code>analogy</code>. This function will get two lists of words (one for positive words and one for negative words), just like the <code>most_similar()</code> method we discussed above.

```
In [24]: from numpy.linalg import norm

def analogy(positive, negative, vectors, index_to_key, key_to_index, topn=10):
```

```
# find ids for positive and negative words
pos_ids = [key_to_index[word] for word in positive]
neg_ids = [key_to_index[word] for word in negative]
given_word_ids = pos_ids + neg_ids
# get embeddings for positive and negative words
pos emb = np.sum(vectors[pos ids], axis=0)
neg_emb = np.sum(vectors[neg_ids], axis=0)
# get embedding for analogy
emb = pos_emb - neg_emb
# normalize embedding
emb = emb / norm(emb)
# calculate similarities to all words in outA vocabulary
similarities = np.dot(vectors, emb)
# get word_ids in ascending order with respect to similarity score
ids ascending = np.argsort(similarities)
# reverse word ids
ids_descending = ids_ascending[::-1]
# get boolean array with element corresponding to any of given word ids set to fal
given_words_mask = np.ones(len(ids_descending), dtype=bool)
given_words_mask[given_word_ids] = False
# obtain new array of indices that doesn't contain any of the given word ids
ids_descending = ids_descending[given_words_mask]
# get topn word_ids
top_ids = ids_descending[:topn]
# retrieve topn words with their corresponding similarity score
top_words = [(index_to_key[idx], similarities[idx]) for idx in top_ids]
# return results
return top words
```

Let's try this function with the $king-m\ddot{a}n+wo\ddot{m}anpprox qu\ddot{e}en$ example we discussed above.

```
In [25]: positive = ["king", "woman"]
    negative = ["man"]
    vectors = glove.get_normed_vectors()
    index_to_key = glove.index_to_key
    key_to_index = glove.key_to_index
    analogy(positive, negative, vectors, index_to_key, key_to_index)
```
